Implementing Quantile Selection Models in Stata*

Ercio Muñoz[†] Mariel Siravegna[‡]

March 6, 2021

Abstract

This article describes **qregsel**, a Stata module to implement a copula-based sample selection correction for quantile regression recently proposed by Arellano and Bonhomme (2017, Econometrica 85(1): 1-28). The command allows the user to model selection in quantile regressions using either a Gaussian or an one-dimensional Frank copula. We illustrate the use of **qregsel** with two examples. First, we apply the method to the fictional data set employed in the Stata base reference manual for the heckman command. Second, we replicate part of the empirical application of the original paper using data for the UK that covers the period 1978-2000 to compare wages of males and females at different quantiles.

Keywords: sample selection, quantile regression, copula method

^{*}We thank Jim Albrecht, Wim Vijverberg, and the participants of the 2020 Virtual Stata Conference for useful comments and suggestions. First draft: April 2020.

1 Introduction

Non-random sample selection is a well known issue in empirical economics. Since the seminal work of Heckman (1979) addressing this problem, much progress has been made in methods that extend the original model or relax some of its assumptions. For example, Vella (1998) provides a survey of methods for estimating models with sample selection bias in this line.

Although most of the effort has been focused on models that estimate the conditional mean, the literature in econometrics has also tackled the problem of non-random sample selection in the context of quantile regression. For example, Arellano and Bonhomme (2017a) offer a survey of recently proposed methods with a focus on a copula-based sample selection model suggested in Arellano and Bonhomme (2017b).

As discussed in Arellano and Bonhomme (2017a), the flexible copula-based approach has an advantage over methodologies that are based on the control function approach. The latter impose conditions on the data that may not be compatible with quantile models if the model is non-additive with non-linear quantile curves on the selected sample (see Huber and Melly (2015)).

In this paper, we briefly discuss the copula-based approach proposed by Arellano and Bonhomme (2017b) and present a new Stata module called **qregsel** that implements it. In addition, we illustrate the method with two empirical examples. First, we estimate a quantile regression model with sample selection using the Stata base reference manual example for the **heckman** command. Second, we replicate the analysis of wage inequality in the UK for the period 1978-2000 as in the original paper.

The paper is organized as follows. Section 2 describes the methodology. Section 3 describes the qregsel command and its syntax. In section 4 we illustrate the use of the command with the empirical examples, and we conclude in Section 5.

2 Methodology

In this section we briefly review the quantile selection model of Arellano and Bonhomme (2017b). The goal is to obtain a consistent estimator when there is sample selection in a non-additive model, such as quantile regression, which precludes the use of the control function approach. The assumption of additive separability of observables and unobservables in the output equation does not hold in general, as argued by Huber and Melly (2015) in the context of testing.

2.1 The Model

Sample selection is modeled using a bivariate cumulative distribution function or copula of the percentile error in the latent outcome equation and the error in the sample

^{1.} A copula-based maximum-likelihood method for the conditional mean is already available in Stata (see Hasebe (2013)).

selection equation. The copula parameters are estimated by minimizing a method-of-moments criterion that exploits variation in excluded regressors to achieve credible identification. Then the quantile regression parameters are obtained by minimizing a rotated check function, which preserves the linear programming structure of the standard linear quantile regression (see Koenker and Bassett (1978)).

Consider a general outcome equation specification where the quantile functions are linear:

$$Y^* = Q(U, X) = x'\beta(\tau) \tag{1}$$

where Y^* is the the latent outcome variable (e.g. wage offers), the function Q is the τ -th conditional quantile of Y^* given the covariates X (e.g. education, experience, etc.), and U is the error term of the outcome equation.

The participation equation is defined as:

$$D = I\{V \le p(Z)\}\tag{2}$$

where D takes values equal to 1 when the latent variable is observable (e.g. employment) and 0 otherwise, Z contains X and at least one covariate B that do not appear in the outcome equation (e.g., a determinant of employment that does not affect wages directly), p(Z) is a propensity score, and V is an error term of the selection equation. Hence, we observe (Y,D,Z) where $Y=Y^*$ only when D=1.

Under the set of assumptions² detailed in Arellano and Bonhomme (2017b), we have that the cdf of Y^* conditional on participation and for all $\tau \in (0,1)$ is:

$$Pr(Y^* < x'\beta(\tau)|D = 1, Z = z) = Pr(U < \tau|V < p(z), Z = z) = G_x(\tau, p(z))$$
 (3)

where $G_x \equiv C(\tau,p)/p$ is the conditional copula function, which measures the dependence between U and V. Here G_x maps rank τ in the distribution of latent outcomes (given X=x) to ranks $G_x(\tau,p(z))$ in the distribution of observed outcomes conditional on participation (given Z=z). Namely, the conditional $G_x(\tau,p(z))$ -quantile of observed outcomes (that is, when D=1) coincides with the conditional τ -quantile of latent outcomes, which implies that if we are able to estimate the mapping $G_x(\tau,p)$ from latent to observed ranks, we are able to recover $Q(\tau,x)$ from the observed outcomes (i.e. we are able to estimate the τ -quantile correcting for selection).

To implement the method, we assume that the copula function is indexed by a single parameter such that:

$$G_x(\tau, p) \equiv G(\tau, p; \rho) = \frac{C(\tau, p; \rho)}{p}$$
 (4)

where the numerator is the unconditional copula of (U, V), the denominator is the propensity score, and ρ is the copula parameter that governs the dependence between the error in the outcome equation and the error in the participation decision.

^{2.} Assumptions: 1) Z is independent of (U,V)|X (exclusion restriction), 2) absolutely continuous bivariate distribution of (U,V)|X=x with standard uniform marginals and rectangular support, 3) continuous outcome, and 4) propensity score, p(z)>0 with probability 1.

2.2 Estimation

Arellano and Bonhomme (2017b)'s estimation algorithm can be summarized in 3 steps: estimation of the propensity score, estimation of the degree of selection via the cumulative distribution function of the percentile error in the outcome equation and the error in the participation decision, and then, using the estimated parameter, the computation of quantile estimates through rotated quantile regression.

The first step consists of estimating the propensity score γ by a probit regression:

$$\hat{\gamma} = argmax_a \sum_{i=1}^{N} D_i ln\Phi(Z_i'a) + (1 - D_i) ln\Phi(-Z_i'a)$$
(5)

The second step is to estimate ρ by minimizing a method-of-moments objective function, which allow us to obtain an observation-specific measure of dependence between the rank error in the equation of interest and the rank error in the selection equation. This is accomplished with a grid search over different values of ρ such that:

$$\hat{\rho} = argmin_c \| \sum_{i=1}^{N} \sum_{l=1}^{L} D_i \varphi(\tau_l, Z_i) [\mathbf{1}\{Y_i \le X_i' \hat{\beta}(\tau_l, c)\} - G(\tau_l, \Phi(Z_i'; \hat{\gamma}), c)] \|$$
 (6)

where $\|.\|$ is the Euclidean norm, $\tau_1 < \tau_2 < \ldots < \tau_L$ is a finite grid on (0,1), and the instrument functions are defined as $\varphi(\tau, Z_i)$ where the dim $\varphi \leq \dim \rho$ and:

$$\hat{\beta}_{\tau}(c) = argmin_{b(\tau)} \sum_{i=1}^{N} D_{i}[G(\tau, \Phi(Z'_{i}\hat{\gamma}); c)(Y_{i} - X'_{i}b(\tau))^{+} +$$
(7)

$$(1 - G(\tau, \Phi(Z_i'\hat{\gamma}); c))(Y_i - X_i'b(\tau))^{-}]$$
(8)

where $a^+ = max\{a, 0\}$, $a^- = max\{-a, 0\}$, and the grid of τ values on the unit interval as well as the instrument function are chosen by the researcher.³

Lastly, using $\hat{\gamma}$ and $\hat{\rho}$ obtained above, the third step consists in computing $\hat{G}_{\tau i} = G(\tau, \Phi(Z_i'\hat{\gamma}); \hat{\rho})$ for all i to estimate $\beta(\tau)$ by minimizing a rotated check function of the form:

$$\hat{\beta}(\tau) = argmin_{b(\tau)} \sum_{i=1}^{N} D_i [\hat{G}_{\tau i} (Y_i - X_i' b(\tau))^+ + (1 - \hat{G}_{\tau i}) (Y_i - X_i' b(\tau))^-]$$
 (9)

where $\hat{\beta}(\tau)$ will be a consistent estimator of the τ -th quantile regression coefficient.

Note that the third step is unnecessary if the quantiles of interest are included in the set $\tau_1 < \tau_2 < \ldots < \tau_L$ used in the second step.

^{3.} In our implementation we use a grid of 9 values (0.1,0.2,...,0.9), and $\varphi(\tau_l, Z_i) = \varphi(Z_i) = p(Z_i; \hat{\rho})$ as in Arellano and Bonhomme (2017b) empirical example.

2.3 Copulas

The Arellano and Bonhomme (2017a) analysis covers the case where the copula is left unrestricted but for the implementation they focus on the case of identification where the copula depends on a low-dimensional vector of parameters.

In our empirical implementation, we only consider the case of a reduced set of onedimensional copulas. We include the Gaussian and an one-parameter Frank. Table 1 provides their respective functional forms.

Table 1: Copula functions Copula name $C(U,V;\rho)$ Range of ρ Gaussian $\Phi_2\{\Phi^{-1}(U),\Phi^{-1}(V);\rho\}$ $-1 \le \rho \le 1$ Frank $-\rho^{-1}log\{1+\frac{(e^{-\rho U}-1)(e^{-\rho V}-1)}{(e^{-\rho}-1)}\}$ $-\infty \le \rho \le \infty$

2.4 Measures of dependence

The parameter ρ that governs the degree of dependence is not directly comparable across copulas (see Hasebe (2013)). For this reason, researchers often report Kendall's τ or the Spearman rank correlation coefficient as a measure of the degree of dependence. Both measures take the range of [-1,1], where a value closer to 1 (-1) indicates a stronger (negative) dependence, and in the case of our copulas can be expressed as closed form in terms of ρ (see Table 2).

Table 2: Copula functions and measures of dependence

Copula name	Range of ρ Kendall's τ		Spearman's rank correlation		
Gaussian	$-1 \le \rho \le 1$	$\frac{2}{\pi}sin^{-1}(\rho)$	$\frac{6}{\pi}sin^{-1}(\rho/2)$		
Frank	$-\infty \le \rho \le \infty$	$1 + \frac{4}{\rho} \{ D_1(\rho) - 1 \}$	$1 + \frac{12}{\rho} \{ D_2(\rho) - D_1(\rho) \}$		

Notes: $D_n(\rho)$ is a Debye function, where $D_n(\rho) = \frac{n}{\rho^n} \int_0^{\rho} \frac{t^n}{e^t - 1} dt$.

2.5 Rotated quantile regression

As previously mentioned, the quantile estimates are obtained by minimizing a rotated check function (See equation 9). The minimization problem can be written as the

following linear programming problem:⁴

$$Min_{\beta_{\tau},u,v} \sum_{i=1}^{N} \hat{G}_{\tau i} u_i + (1 - \hat{G}_{\tau i}) v_i$$
 (10)

such that:

$$\mathbf{y} - \mathbf{X}\beta_{\tau} = \mathbf{u} - \mathbf{v} \tag{11}$$

$$\mathbf{u} \ge \mathbf{0}_n \tag{12}$$

$$\mathbf{v} \ge \mathbf{0}_n \tag{13}$$

where $\mathbf{0}_n$ is a vector of 0s, \mathbf{X} is the matrix of observations of the covariates, \mathbf{y} is the vector of observations of the outcome, and \mathbf{u} and \mathbf{v} are added to the inequality constraint to transform it into an equality.

This linear programming problem could be solved using the LinearProgram() class in Stata or alternatively using the Stata integration with Python. However, we implement an interior point algorithm developed by Portnoy and Koenker (1997) by translating the Matlab code used by Arellano and Bonhomme (2017b) to Mata language.⁵

3 The gregsel command

In this section we describe the **qregsel** command to implement a copula-based sample selection correction in quantile regression.

3.1 Syntax

The syntax of the qregsel command is:

3.2 Options

 $select([depvar_S =] varlist_S)$ specifies the selection equation. If $depvar_S$ is specified, it should be coded as 0 and 1, with 0 indicating an outcome not observed for an observation and 1 indicating an outcome observed for an observation. select() is required.

^{4.} This closely follows the quantile regression example for linear programming available in the Mata reference manual (see example 3 for LinearProgram() in StataCorp (2019a)).

^{5.} The Matlab's routine was originally written by Daniel Morillo and Roger Koenker in Ox, translated to Matlab by Paul Eilers, and slightly modified by Roger Koenker. It can be found in the supplemental material of Arellano and Bonhomme (2017b), and in Roger Koenker's website.

quantile(#) estimate # quantiles. quantile() is required.

copula (copula) specifies a copula function governing the dependence between the errors in the outcome equation and selection equation. copula may be gaussian or frank. The default is copula (gaussian).

noconstant suppresses the constant term in the outcome equation.

finergrid finds the value of the copula parameter using a grid of 199 values (values such that the Spearman rank correlation is approximately [-0.99,-0.985,...,0.985,0.99]) instead of 100 (values such that the Spearman rank correlation is approximately [-0.99,-0.98,...,0.98,0.99]), as done by default.

coarsergrid finds the value of the copula parameter using a grid of 50 values (values such that the Spearman rank correlation is approximately [-0.99,-0.95,..,0.93,0.97]) instead of 100 (values such that the Spearman rank correlation is approximately [-0.99,-0.98,..,0.98,0.99]), as done by default.

rescale transforms the independent variables in the outcome equation by subtracting from each its sample mean and dividing each by its standard deviation.

nodots suppresses progress dots that indicate status over the grid search.

3.3 Returned values

qregsel saves the following in e():

Scalars e(N) e(rho) e(spearman)	Number of observations Copula parameter Spearman's rank correlation	e(N_selected) e(kendall)	Number of selected observations Kendall's tau
Macros			
e(copula) e(indepvars) e(outcome_eq) e(cmd) e(rescale) e(properties)	Specified copula Independent variables Outcome equation Command name Use of rescale option b	e(depvar) e(cmdline) e(select_eq) e(predict) e(title)	Dependent variable Command line Selection equation Predict command name Quantile selection model
Matrices			
e(b)	Coefficient vector	e(grid)	Matrix with the values of the objective function for each value of rho, and its respective Spearman rank correlation and Kendall's tau
e(coefs)	Coefficient matrix		
Functions e(sample)	Marks estimation sample		

3.4 Prediction

After the execution of qregsel, the predict command is available to compute a counterfactual of the outcome variable corrected for sample selection. Here is its syntax:

predict newvarlist [if][in]

where the list of new variables must contain two new variable names, the first one for the counterfactual outcome variable, and the second one for a binary indicator of selection, to be generated respectively.

The counterfactual outcomes are constructed by randomly generating an integer q between 1 and 99 for each individual in the full sample, and then using the quantile coefficients associated with each draw of q to produce a prediction of the qth quantile of the outcome distribution. This approach follows the conditional quantile decomposition method of Machado and Mata (2005) and has been recently applied for example in Bollinger et al. (2019).

The selection indicator is generated by randomly drawing values of the error in the selection equation V from the conditional distribution of V given U=u, derived from the chosen copula using the estimated copula parameter and the values of U randomly generated to create the counterfactual outcome variable in the previous paragraph. This approach follows the empirical exercise performed in Arellano and Bonhomme (2017b).

3.5 Inference

Confidence intervals for any of the parameters can be estimated using methods such as the conventional nonparametric bootstrap, or alternatively using subsampling (Politis et al. (1999)) as done in Arellano and Bonhomme (2017b) due to the computational advantage when using large sample sizes.

In our first empirical application we illustrate how to use bootstrap to create a confidence interval for the estimated coefficients of the quantile regression and the copula parameter.

4 Empirical Examples

In this section we illustrate the use of the command with two empirical examples. First, we use the classic example of wages of women in which we use the data available from the Stata manual example for the command heckman. Second, we replicate part of an exercise presented in Arellano and Bonhomme (2017b) with data from the UK.

4.1 Wages of women

In this application we use the fictional data set used in the documentation of the Heckman selection model in the Stata base reference manual (see StataCorp 2019b) to study wages of women. As in the example, we assume that the hourly wage is a function of education and age, whereas the likelihood of working (and hence the wage being observed) is a function of marital status, the number of children at home, and (implicitly) the wage (via the inclusion of age and education). We do not take the logarithm of

wage as it is usually done, however the variable in the fictional data set has already a bell-shaped histogram. In addition, we follow the example in the Stata 16 base reference manual by not including squared age as it is standard in this type of regression.

First, we estimate a quantile regression over the quantiles 0.1, 0.5, and 0.9 without corrections for sample selection as a benchmark.

```

Next we turn to the estimation of a quantile regression accounting for sample selection by using the command qregsel with a Gaussian copula. In addition, we plot the value of the objective function over the minimization grid (see Figure 1). The value of rho that minimizes the criterion function is approximately equal to -0.65, as stored in e(rho). The interpretation of this estimated value is that women with higher wages (higher U) tend to participate more (lower V).

Copula parameter (gaussian): -0.65wage Coef. q10 education 1.112866 .204362 age -8.498507 _cons q50 1.017025 ${\tt education}$.2028979 age _cons .5828089 q90 .8888879 education.2272004 age 8.914994 _cons . ereturn list scalars: e(N) = 2000 $e(N_selected) = 1343$ e(rho) = -.647834836e(kendall) = -.43389025e(spearman) = -.63macros: e(copula) : "gaussian" e(depvar) : "wage" e(indepvars) : "education age _cons" e(cmdline) : "qregsel wage education age, select(married children educ age)" e(outcome_eq) : "wage education age" e(select_eq) : "married children educ age" e(cmd) : "qregsel" e(predict) : "qregsel_p" e(rescale) : "non-rescaled" e(title) : "Quantile selection model" e(properties) : "b" matrices: $e(b) : 1 \times 9$ e(grid): 100 x 4 e(coefs) : 3 x 3functions: e(sample)

After the estimation a counterfactual distribution that is corrected for sample selection may be generated with the post estimation command predict as follows. Figure 2 displays the ventiles of the distribution corrected for sample selection versus the uncorrected one. We can see how wages are lower after correcting for selection at each ventile of the distribution.

4.2 Wage inequality in UK

In this example we apply the model to measure market-level changes in wage inequality in the UK. We compare wages of males and females at different quantiles of the wage distribution, correcting for selection into work. We replicate Arellano and Bonhomme (2017b) using the data set provided by the authors, which originally comes from the Family Expenditure Survey (FES) from 1978 to 2000.

We model log-hourly wages Y and employment status D. The controls X include linear, quadratic, and cubic time trends, four cohort dummies (born in 1919-1934, 1935-1944, 1955-1964, and 1965-1977, omitting 1945-1954), two education dummies (end of schooling at 17 or 18, and end of schooling after 18), 11 regional dummies, marital status, and the number of kids split by age categories (six dummies, from 1 year old to 17-18 years old).

The excluded regressor follows Blundell et al. (2003) and corresponds to their measure of potential out-of-work (welfare) income, interacted with marital status. This variable was constructed for each individual in the sample using the Institute of Fiscal Studies tax and welfare-benefit simulation model.

Arellano and Bonhomme (2017b) estimate the sample selection model independently by gender and marital status. We replicate (see code below) the exercise reported in the paper using a Frank copula and find that the copula parameter in the case of married individuals is -1.548 for males and -1.035 for females (the associated rank correlations are -0.250 and -0.170, respectively). For single individuals is -7.638 for males and -0.421 for females (the respective rank correlations are -0.790 and -0.070). After the estimation using each sub-sample, we use predict to generate counterfactual outcomes, which are then used to plot quantiles by gender with and without correction for sample selection over time. We are able to replicate the empirical facts documented in the original paper (see Figure 3). We see that correcting for sample selection makes an important

difference at the bottom of the wage distribution for males while the difference seems to be less important in the case of women.

Figure 3: Wage quantiles, by gender

Notes: Quantiles of log-hourly wages, conditional on employment (solid lines) and corrected for selection (dashed). Male wages are plotted in thick lines, while female wages are in thin lines.

5 Concluding remarks

In this article, we introduce a new Stata module called qregsel, which implements a copula-based method proposed in Arellano and Bonhomme (2017b) to correct for sample selection in quantile regressions. The use of the command is illustrated with two empirical examples.

Additional empirical applications of the econometric method here introduced include

the analysis of the gender gap between earnings distributions in Maasoumi and Wang (2019), and the analysis of earnings inequality correcting for non-response in Bollinger et al. (2019).
